# INTRODUCTION TO AIRCRAFT STRUCTURES : COMPOSITE STRUCTURES

---

Or 'A weight saving alternative to a metallic structure'

# COMPOSITE STRUCTURES

- Reference: Composite Materials in Aircraft Structures, Ed. D.H.Middleton, Longman
- **Material Characteristics**
  - Orthotropic
  - Excellent fibre direction properties (Fibre in tension / compression)
  - Transverse properties much reduced (Resin in tension / compression)
  - Linear Elastic strain to failure
  - Notch sensitive for static loads but less sensitivity under cyclic loads
  - Can be prone to delamination if structure design and manufacture is not good

# COMPOSITE STRUCTURES

- **Materials**

- **Carbon/epoxy**

- Good strength and stiffness
- Can be expensive

- **Glass/epoxy**

- Properties generally not as good as Carbon
- Generally cheaper
- Radar transparent

# COMPOSITE STRUCTURES

- **Kevlar**
  - Good in tension
  - Poor compressive strength
  - Good energy absorption in laminate form
  - More sensitive to Environment & difficult to machine
- **Woven Materials**
  - Tows (bundles of fibres) woven to make 0/90 blanket
  - Easier to handle
  - Easier to lay on curved surfaces
  - Crimping reduces properties

# COMPOSITE STRUCTURES

## • Typical Composite Material Property notations

### • Ref MIL-HNDBK-17-3F

- US DEPARTMENT OF DEFENSE HANDBOOK
- COMPOSITE MATERIALS HANDBOOK
- VOLUME 3. POLYMER MATRIX COMPOSITES
- MATERIALS USAGE, DESIGN, AND ANALYSIS

Notation =  $H_i^j k$   
Where,

$H = \begin{cases} \sigma, \tau; \text{Applied Normal, Shear Stress} \\ F; \text{Allowable Stress} \\ \epsilon, \gamma; \text{Extensional, Shear Strain} \\ E, G; \text{Young's, Shear Modulus} \\ \nu; \text{Poisson's Ratio} \end{cases}$

Note:  $\nu_{12}^1 = \text{Major Poisson's Ratio} = -\frac{\epsilon_2}{\epsilon_1}$

$\nu_{21}^1 = \text{Minor Poisson's Ratio} = -\frac{\epsilon_1}{\epsilon_2}$

$i = \begin{cases} 1; \text{Longitudinal} \\ 2; \text{Transverse} \\ 3; \text{Thickness} \\ 12, 13, 32; \text{Shear, Poisson's} \end{cases} \begin{cases} \text{Lamina} \\ \text{Laminate} \end{cases}$

$j = \begin{cases} c; \text{Compression} \\ t; \text{Tension} \\ s; \text{Shear} \end{cases}$

$k = \begin{cases} y; \text{Yield} \\ u; \text{Ultimate, Not Used for Stiffness} \end{cases}$

Examples,  $F_2^{tu}$  = Lamina Ultimate Transverse Tensile Allowable Stress

$E_z^c$  = Laminate Compressive Young's Modulus, Thickness Direction

# COMPOSITE STRUCTURES

- **Typical Composite Material Properties vs Other Aerospace Materials**

Material	Density $\rho$ $\text{g} / \text{mm}^3$ $* 10^{-3}$	Tensile Modulus $E$ (Gpa)	Tensile Strength $\sigma$ (Mpa)	Specific Modulus ( $E / \rho$ )	Specific Strength ( $\sigma / \rho$ )
Aluminium 7075 T6	2.8	72	570	26	204
Titanium 6Al 4V	4.5	114	1000	25	222
Steel S 300	8.0	207	2000	26	250
Carbon / Epoxy T800 UD	1.8	154	2570	86	1427

# COMPOSITE STRUCTURES

- Sandwich Construction
- Core materials:
  - Aluminium honeycomb
  - Nomex honeycomb
  - Foam (closed & open cell)
- Good bending stiffness and light weight

# COMPOSITE STRUCTURES

- **Sandwich Construction**
- **Manufacture**
  - Co-cured – skins cured and bonded to core in single operation.
  - Secondary bonded – procured skins bonded to core in second step.
- **Potential Additional problems**
  - Core failure
  - Debonding
  - Moisture ingress

# COMPOSITE STRUCTURES

- **Layups**
- Standardised ply orientations normally used: 0/+45/-45/90
- Quasi-isotropic – “black aluminium” (25/50/25 Lay-up)
- Equal thickness of 0/90/+45/-45 plies
- Balance and Symmetry preferred – avoids distortion during cure and bending under in-plane loading.
- Orthotropic – layup tailored to loads in different directions e.g. 0/+45/-45
- Unidirectional – structurally most efficient if loads are in one direction, but must avoid excess transverse loading.

# COMPOSITE STRUCTURES

- **Typical Spar & Cover Layups can be derived by thinking about what type of loading the structure has to carry**
- **Skin / stringer 'wing cover' carries axial load and torsional shear :**
- **Typical layup would be 50/40/10 or 60/30/10 (dominance of 0 deg fibres)**
- **Spar webs carry shear load :**
- **Typical layup would be 10/80/10 (dominance of  $\pm 45$  deg fibres)**

# COMPOSITE STRUCTURES

- **Manufacturing Methods**

- **Wet lay-up**

- Resin is applied to dry fibre blankets in a mould, and cured under a vacuum bag at room temperature or with a heater mat.
- Labour intensive and relatively low technology approach, used mainly for boats, gliders and light aircraft.
- Quality is not so high due to difficulties in controlling resin content, maintaining fibre geometry and avoiding porosity.

# COMPOSITE STRUCTURES

- **Prepreg**

- Fibres are pre-impregnated with resin and partially cured to form plies typically 0.125 mm to 0.25 mm lamina thickness.
- Plies are laid up over tooling and cured in an autoclave at temperature, under pressure and with a vacuum bag.
- Much higher quality than wet lay-up, but more expensive.
- Lay-up can be automated with tape laying or fibre placement machines.
- Most widely used process for aerospace structures.

# COMPOSITE STRUCTURES

- Coriolis Automated Fibre Placement at UK NCC (Bristol)

# COMPOSITE STRUCTURES

- **Filament winding**
  - Tow of resin impregnated fibres wound onto a mandrel under tension. Can also be done with strips of prepreg tape.
  - Good for components which are axisymmetric e.g. pressure vessels, but geometry and lay-ups are restricted.

# COMPOSITE STRUCTURES

- **Resin Transfer Moulding**
- Liquid resin is infused into a dry fibre preform in a closed mould.
- Can produce complex parts in a single process.

# COMPOSITE STRUCTURES

- **Critical design issues**
- **Delamination**
- Delamination due to low through thickness strength is a major cause of failure in composite structures.
- Through thickness stresses arise from out-of-plane loading or from geometrical features such as bends and changes in thickness.
- **Compression after impact (CAI)**
- Composites are susceptible to impact damage due to low through thickness strength.
- Damage may not be visible, but can greatly reduce compressive strength due to buckling between delaminated plies.

# COMPOSITE STRUCTURES

- **Notched strength**
- Composites are more brittle and show large reductions in static strength when notched.
- **Hot/wet properties**
- Matrices soften at high temperatures and in the presence of moisture, leading to reduction in strength, especially in compression.

# COMPOSITE STRUCTURES

- **Transverse cracking**
- 90° ply cracks can occur at relatively low stresses. These generally have little effect on static strength, but may cause delamination in fatigue or leakage in pressure vessels.
- Transverse cracking can be reduced by avoiding thick blocks of plies of the same orientation.

# COMPOSITE STRUCTURES

- **Repair**
- Repair needs to be taken into account at the design stage. For example in a bonded structure it may be necessary to allow enough space and strength margin for a bolted repair.
- **Lightning strike**
- Lightning can cause large local damage due to poor conductivity. Metal strips or meshes need to be incorporated in vulnerable areas to provide a conducting path.
